## Floristic list and biological spectra of plants of Arrang Sire Ghar, Bajaur district of Khyber Pakhtunkhwa, Pakistan

**Shakir Ullah, Lubna Begam, Fozia Abasi, Siraj Khan, Imran Bacha, Mohammad Sohil and Mohsin Ihsan**

### Abstract

A List of plant species of Bajaur District was set on the basis of field trips conducted in different parts of the year 2018, mostly in, summer, monsoon and winter. The flora comprised of 167 plant species belonging to 40 families. The leading families are Lamiaceae, Solanaceae and Asteraceae, which have 16 species, followed by Mimosaceae and Euphorbiaceae, 11 Zygophyllaceae 8 and Moraceae, with 7 species. Each of the Poaceae, Rhamnaceae, Verbenaceae Papilionaceae, Capparidaceae, Amaranthaceae and Apocynaceae had 3 species, while Buxaceae, Asclepiadaceae, Nyctaginaceae, Oleaceae, Plantaginaceae, Polygonaceae Cannabinaceae, Celastraceae, Cucurbitaceae, Cyperaceae, Liliaceae, Acanthaceae, Aclepidaceae, Meliaceae, Sapindaceae and Sapotaceae had 2 species each. The biological spectrum showed that Hemicryptophytes (05 spp., 9.26%), geophytes (03 spp., 5.56%), chamaephytes (06 spp., 11.1%), Nanophanerophytes (10 spp., 18.5%), megaphanerophytes (14 spp., 25.9%), Therophytes (16 spp., 29.6%). Leaf spectra of plants comprised of nanophylls (5.56%), megaphylls (1.85%) leptophylls (16.7%), microphylls (50%) and mesophylls (25.9%).

**Keywords:** Floristic list, biological spectra, arang sire ghar, Bajaur district Pakistan

### 1. Introduction

The ancient name of Bajaur was Nardem, meaning a narrow sprout in Kohistani language. It was its name when the ancient aboriginal people lived here. When the Gabari tribe of Persian origin occupied the land its name was changed to Gabar Swat as both the regions were included in its domain (Ali *et al.*, 2017) [1]. The name of Bajaur was coined for the area during Sultanate Period of Dehli, when a ruling tribe by the name of "Arab Bajaur" used to exhort taxes and Tithes on the produce (Baj) from the local people and then send the same to Delhi. So Baj and Aurdan have been mixed in to Bajor or Bajaur (Nisarand Ali, 2012). It is one of the seven Agencies, comprising FATA (Federally Administered Tribal Areas), along with the 5 FRS (Frontier Regions). The geographical boundaries of Bajaur have been shifted more frequently and drastically than any region of Pakistan. There was a time when all the territory between the Kunar River and Panjkora was included in Bajaur (Aziz *et al.*, 2017) [4]. A large portion of Mohmand Agency was also included but these days it has been squeezed to its present diminished position. It is bordered by the Kunar province of Afghanistan to its north-west and has a common border of 52 kilometers, starting from the pass of Shahi in the north up to the Nawa pass in the west (Aziz *et al.*, 2018) [3]. And this border with Kunar province provides very strategic importance not only to Bajaur but to Pakistan also. To its south-east is located the Malakand Agency; Dir district of KPK (Khyber Pakhtunkhwa) is lying to the north-east and Mohmand Agency to its south-west (Shuaib *et al.*, 2018) [17]. The land mass of present day Bajaur Agency is actually perched on a slope and gradually tilting and bending downwardly from the Kunar ridge in the direction of Panjkora River in the east. Drainage of Bajaur is flowing to the east and this flow starts from the dividing ridge's eastern slopes that overlook the Kunar in Afghanistan (Iqbal *et al.*, 2015) [8]. Both non-cultivated plants and non-domesticated animals are come in this category. Besides the domestic animals such as cow, buffalo, goat, sheep, ox, horse, donkey, ass, mule, dog, cat and cock, there are numerous other wild animals found in jungles, gorges, ravine and grasslands. Chakor, monal pheasant, cranes, owl, wood pecker, sparrow, black and brown partridges, Porcupine, snake, rabbit, coyote, jackals, crows, lizards, spiders, duck, parrots,

monkeys, long horns and dozens of birds and insects are found in Bajaur Agency. The vegetation in Malasid Hills show great variation with the change in climate and depends upon rains and other geographic factors (Zaman *et al.*, 2018) [9]. Broadly speaking, the vegetation of Malasid Hills is distributed in these zones, depending upon the elevation (Rahman *et al.*, 2018) [13]. It comprises many diverse species, particularly of grasses, that tolerate grazing. Moreover several kinds of flowering herbs, shrubs, wild roses and thorns configure thick vegetation. The non-thorny plants heave a sigh of relief in the presence of thorny plants. Roaming among the dales of Malasid, one comes across meadows of sweet-scented hay, the sweet vernal grass (Aziz *et al.*, 2018). This grass contains the aromatic compound Coumarin in great quantities. The dominant plant species of Malasid Hills are Kharawa (*Cotoneaster affinis*), Khar Ghwag (*Verbascum Thapsus*), Batoora (*Datura Stramonium*), Maraghoonay (*Solanum surratens*), Koteelal (*Wlhania somnifera*), Dambara (*Zanthoxylem armatum*), Markhanai (*Ziziphus mauritiana*), Ghwarija (*Indigofera heterantha*), Khona (*Olea ferruginea*), Inzar (*Ficus palmata*), Palosa (*Acacia modesta*), Gooti (*Ajuga bracteosa*), Ghooz (*Juglans reggia*), Seerai (*Quercus incana*), Geeray (*Alnus nitida*), Kwaray (*Berberis lyceum*), Spulmai (*Calatropis procera*), Gandiray (*Nerium oleander*), Sharghashay (*Saccharum spontaneum*), Nakhtar (*Pinus roxburghii*), Chinar (*Platanus orientalis*) and hundreds of others are some of the common species of this zone (Jamal *et al.*, 2018) [9].

## 2. Materials and Methods

### 2.1 Study area

The area of Arang Sire Ghar was selected for vegetation surveying and analysis. This area was not selected for ecological evaluation of vegetation earlier before. The detailed surveys and vegetation sampling accomplished in 2 different. The duration of spring season is from March to June while that of summer is from July to August. During this period the research area tripped regularly. Collection and preservation of plants carried out carefully. In this regard two types of data in above mentioned seasons were recorded. The equipment e.g. GPS, compass, note book, pencil, papers, bloat papers and labels carried to the area.

### 2.2 Selection of sample sites

Selection of sample sites is necessary before the sampling. For this analysis a total four sites were selected which further divided into three territories that is foot hill, mid hill and top hill vegetation on the basis of physiognomy, edaphic factors and altitude. Each site was consisting of forty eight stands of herbs, shrubs and trees, on this account total twelve stands were obtained. To compare the present status of vegetation with that of past the local people and elder nominated and information gathered. Ecological evaluative study conducted and different samples of vegetation and soil collected from each site. The plants was identified by existing collected works (Ali & Qaisar 1971-

2006). These plant was submitted to the Herbarium, Govt Post Graduate Collage Timargara Lower Dir Pakistan Department of Botany. Into different life form the plants were categorized and leaf size classes as follows after Raunkiaer (1934) [14], Muller and Ellenberg (1974).

**Key Notes**

Life form: THP= Therophytes, HMP= Hemicryptophytes, CHP= Chaemophytes, NPP= Nanophenerophytes, PNP= Penerophytes, MPP= Microphenerophytes, GEP= Geophytes, Hyp= Hydophytes, CRP= Criptophytes.

Leaf form: MIC= Microphyll, MEG= Megaphyll, MSP= Mesophyll, MCP= Macrophyll, NPL= Nanophyll, LTP= Leptophyll, APL= Aphylloous.

Palatability: + = Palatable, - = Non palatable, C= Cow, G= Goat, S= Sheep, B= Buffa

#### 4. Discussion

Life forms of various species recorded from Arang Sire Ghar were classified into major life forms. A bio spectrum is formed when all the species of higher plants are classified into life forms and their ratio expressed in number or percentage (Saxina *et al.*, 1987) [15]. Biological spectra are useful in comparing geographically widely separated plant communities and are also regarded as an indicator of prevailing environment. Occurrence of similar biological spectrum in different regions indicates similar climatic conditions. According to Raunkiaer (1934) [14] the climate of a region, is characterized by life form, while in biological spectrum of the region exceeds the percentage of the same life form. However, due to biological disturbance the proportion of life forms may be altered. Biological spectrum may be materially changed due to introduction of therophytes like annual weeds, due to biotic influences like agricultural practices and grazing, deforestation and trampling etc. The dominance of therophytes (16 spp., 29.6%) in the study area indicated that the investigated area was under heavy biotic pressure due to deforestation and over grazing. Generally, they were more abundant in the spring as it reflected spring aspect. Leaf size spectrum of the plant exposed that Mesophyll species followed by microphyllous species. Steppes are Microphylls are usually, while leptophylls and nanophylls are showed by of hot deserts (Tareen & Qadir, 1993, Cain and Castro, 1959) [18, 6]. The present investigation displays that microphylls and nanophylls were present in high altitudes (1500 m) and leptophylls were high at the foot hills. There are always a flush of annuals during spring, which gives an outlook to the community (Malik & Hussain 1990, Shimwell 1971) [12, 16]. Similar trend regarding prevalence of therophytes was observed by (Hussain *et al.*, 1997). (Saxina *et al.*, 1987) [15] stated that Hemicryptophytes ruled alpine and temperate zones in overlapping and loose continuum. Therophytes survive under adverse condition through seeds production. The predominance of therophytes in variable conditions such as dry, hot or cold met for low to higher elevation might be the reason for their higher percentage in the present study (Qadir and Shetty 1986). A high percentage of microphylls might be due to dry climate in subtropical area. Here the soil was poorly developed with thin sheet that prevented root penetration. Furthermore, roots absorb low moisture and nutrients under dry conditions. In subtropical regions the plant face drought during winter especially in dry soil. The species with microphyllous leaves were abundant due to ecological adaptation for these arid conditions. The present findings agree with those of (Qadir and Tareen, 1987) who reported high percentage of microphylls in the dry temperate climate of Quetta district. These data indicated that the percentage of various leaf form classes varied with increasing altitude. (Saxina *et al.*, 1987) [15] also observed that the percentage of microphylls was positively related with the increasing altitude and this also support our findings. However, in the tropical wet forest, as reported by (Dolph and Dilcher 1980) [7], large leaved species were dominant.
